

# Lexical Analysis: Constructing a Scanner from Regular Expressions

- Show how to construct a FA to recognize any RE
- This Lecture
  - → Convert RE to an nondeterministic finite automaton (NFA)
    - Use Thompson's construction

### Quick Review

Previous class:

- $\rightarrow$  The scanner is the first stage in the front end
- $\rightarrow$  Specifications can be expressed using regular expressions
- $\rightarrow$  Build tables and code from a DFA

Consider the problem of recognizing register names

*Register*  $\rightarrow$  r (0|1|2| ... | 9) (0|1|2| ... | 9)\*

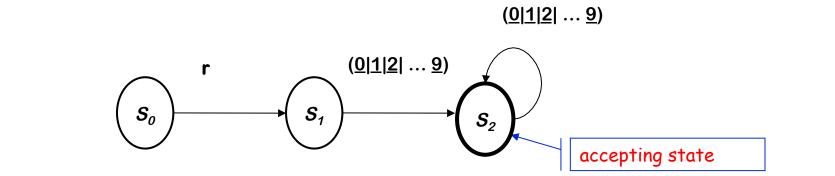

- Allows registers of arbitrary number
- Requires at least one digit

Consider the problem of recognizing register names

*Register*  $\rightarrow$  r (0|1|2| ... | 9) (0|1|2| ... | 9)\*

RE corresponds to a recognizer (or DFA)

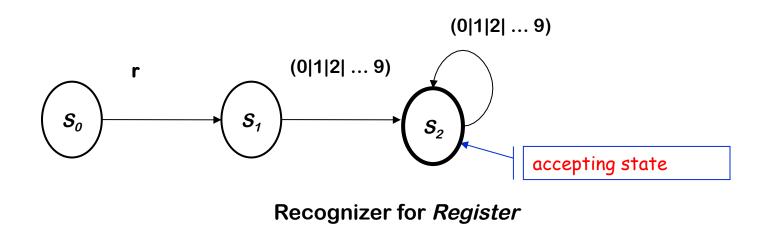

Recognizer for Register

Transitions on other inputs go to an error state,  $s_e$ 

- Start in state  $S_0$  & take transitions on each input character
- DFA accepts a word <u>x iff x</u> leaves it in a final state  $(S_2)$

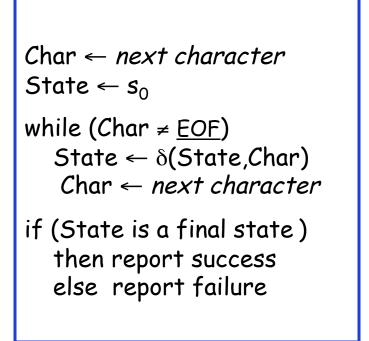

So,

- <u>r17</u> takes it through  $s_0$ ,  $s_1$ ,  $s_2$  and accepts
- <u>r</u> takes it through *s*<sub>0</sub>, *s*<sub>1</sub> and fails
- <u>a</u> takes it straight to  $s_e$

# Example

To be useful, recognizer must turn into code

δ	r	0,1,2,3,4, 5,6,7,8,9	All others
<b>s</b> <sub>0</sub>	\$ <sub>1</sub>	S <sub>e</sub>	S <sub>e</sub>
<b>S</b> 1	S <sub>e</sub>	<b>s</b> <sub>2</sub>	5 <sub>e</sub>
<b>s</b> <sub>2</sub>	S <sub>e</sub>	<b>s</b> <sub>2</sub>	<b>s</b> <sub>e</sub>
S <sub>e</sub>	S <sub>e</sub>	S <sub>e</sub>	s <sub>e</sub>

Skeleton recognizer

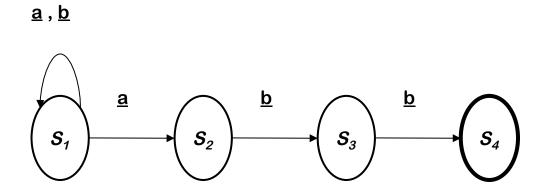

Table encoding RE

Each RE corresponds to a *deterministic finite automaton* (DFA)

• May be hard to directly construct the <u>right</u> DFA

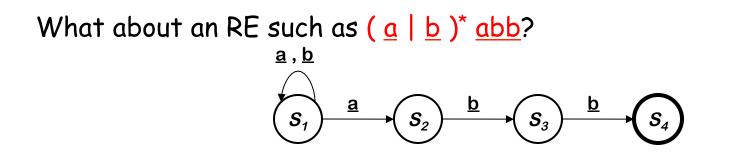

For example, consider the RE ( $\underline{a} \mid \underline{b}$ )\*  $\underline{abb}$ .

Each RE corresponds to a *deterministic finite automaton* (DFA)

• May be hard to directly construct the right DFA

This is a little different from typical DFAs!

• S<sub>1</sub> has two transitions on <u>a</u>

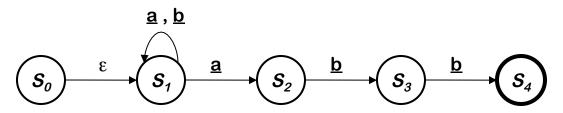

This is a non-deterministic finite automaton (NFA)

Each RE corresponds to a *deterministic finite automaton* (DFA)

• May be hard to directly construct the right DFA

What about an RE such as  $(\underline{a} | \underline{b})^* \underline{abb}$ ?

This is a little different from typical DFAs!

- *S*<sub>1</sub> has two transitions on <u>a</u>
- $S_0$  has a transition on  $\varepsilon$

This is a non-deterministic finite automaton (NFA)

• An NFA accepts a string x

iff  $\exists$  a path though the graph from  $s_0$  to a final state such that the edge labels spell x

- Transitions on  $\epsilon$  consume no input
- To "run" the NFA, start in s<sub>0</sub> and guess the right transition at each choice point with multiple possibilities
  - → Always guess correctly
  - $\rightarrow$  If some sequence of correct guesses accepts x then accept

- They are the key to automating the RE $\rightarrow$ DFA construction
- We can paste together NFAs with  $\epsilon$ -transitions

### Relationship between NFAs and DFAs

DFA is a special case of an NFA

- DFA has no  $\epsilon$  transitions
- DFA's transition function is single-valued
- Same rules will work

DFA can be simulated with an NFA

→ Obviously

# Relationship between NFAs and DFAs

NFA can be simulated with a DFA

(less obvious)

- Simulate sets of possible states
- Possible exponential blowup in the state space
- Still, one state per character in the input stream

Subset construction builds a <u>DFA</u> that simulates an <u>NFA</u>.

# Automating Scanner Construction

To convert a specification into code:

- 1 Write down the RE for the input language
- 2 Build a big NFA
- 3 Build the DFA that simulates the NFA
- 4 Systematically shrink the DFA
- 5 Turn it into code

#### Scanner generators

- Lex, Flex, and JLex work along these lines
- Algorithms are well-known and well-understood
- Key issue is interface to parser *(define all parts of speech)*

# Automating Scanner Construction

 $RE \rightarrow NFA$  (Thompson's construction)

- Build an NFA for each term
- Combine them with  $\epsilon$ -transitions

 $NFA \rightarrow DFA$  (Subset construction)

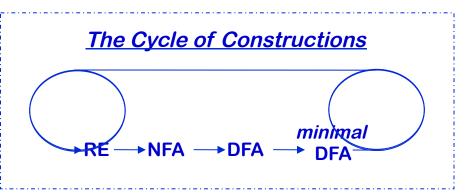

Build the simulation

 $DFA \rightarrow Minimal DFA$ 

Hopcroft's algorithm

 $DFA \rightarrow RE$  (Not part of the scanner construction)

- All pairs, all paths problem
- Take the union of all paths from  $s_0$  to an accepting state

### $RE \rightarrow NFA$ using Thompson's Construction

#### Key idea

- NFA pattern for each symbol and each operator
- Join them with  $\boldsymbol{\epsilon}$  transitions in precedence order

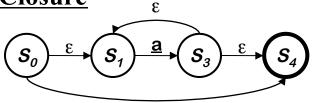

NFA for **b** 

**Concatenation** 

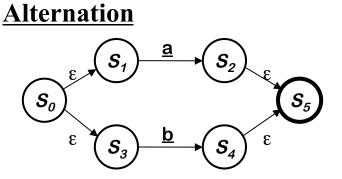

NFA for <u>ab</u>

**Closure** 

ε NFA for <u>a</u>\*

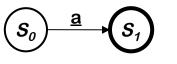

NFA for <u>a | b</u>

Ken Thompson, CACM, 1968

 $RE \rightarrow NFA$  using Thompson's Construction

Let's try:  $a(b|c)^*$ 

NFA for <u>a</u>

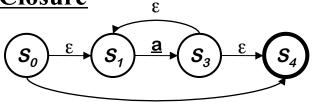

NFA for b

**Concatenation** 

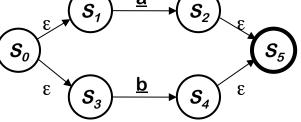

NFA for <u>ab</u>

ε NFA for <u>a</u>\*

**Alternation** <u>a</u>

NFA for  $\underline{a} \mid \underline{b}$ 

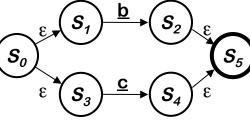

### Example of Thompson's Construction

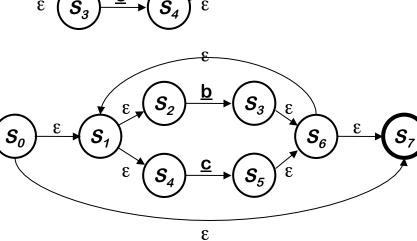

Let's try  $\underline{a} (\underline{b} | \underline{c})^*$ 

1.  $\underline{a}, \underline{b}, \underline{c}$   $(s_0) \xrightarrow{\underline{a}} (s_1) (s_0) \xrightarrow{\underline{b}} (s_1) (s_0) \xrightarrow{\underline{c}} (s_1) (s_1) (s_1) (s_1) (s_2) \xrightarrow{\underline{c}} (s_1) (s_2) (s_1) (s_2) (s_1) (s_2) (s_1) (s_2) (s_2) (s_1) (s_2) (s_2) (s_1) (s_2) (s_2) (s_2) (s_1) (s_2) (s_2$ 

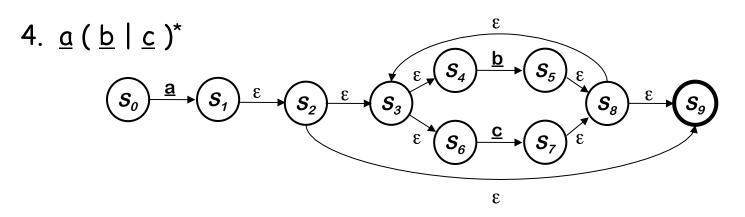

2. <u>b</u> | <u>c</u>

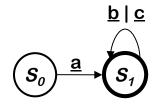

Of course, a human would design something simpler ...

But, we can automate production of the more complex one ...
