Algebraic Distance

Network Science, Spring14 1 / 34

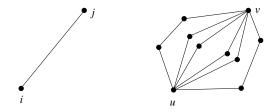

# How to model a connectivity between graph vertices?

Possible problems in (hyper)graph models:

- unweighted edges;
- edges with almost identical weights:  $0.999 \approx$ ? 1.001;
- incomplete set of edges.

# How to model a connectivity between graph vertices?

Possible problems in (hyper)graph models open questions like

- how to break ties?
- should we choose a heaviest edge?
- should we match a disconnected pair?

Some existing approaches

- Shortest path
- All/some (weighted) indirect paths
- Spectral approaches
- Flow network capacity based approaches
- Random-walk approaches: commute time, first-passage time, etc. (Fouss, Pirotte, Renders, Saerens, ...)
- Speed of convergence of the compatible relaxation from AMG (Brandt, Ron, Livne, ...)
- Probabilistic interpretation of a diffusion (Nadler, Lafon, Coifman, Kevrekidis, ...)
- Minimization of effective resistance of a graph (Ghosh, Boyd, Saberi, ...)

Simulation process that shows which pair of vertices tends to be 'more connected' than other.

$$\forall i \in V \text{ define } x_i = rand()$$

Oo k times step 3

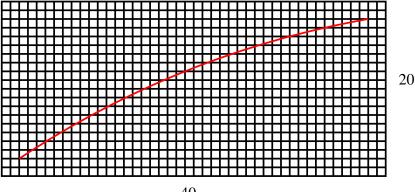

## Conjecture

If  $|x_i - x_j| > |x_u - x_v|$  then the local connectivity between u and v is stronger than that between i and j.

We will call  $s_{ij}^{(k)} = |x_i - x_j|$  the algebraic distance between *i* and *j* after *k* iterations.

## Stationary iterative relaxation

Rewrite the iterative process as  $x^{(k+1)} = Hx^{(k)}$ , where *H*:

$$\begin{aligned} H_{GS} &= (D-L)^{-1}U, & H_{SOR} &= (D/\omega-L)^{-1}\left((1/\omega-1)D+U\right), \\ H_{JAC} &= D^{-1}(L+U), & H_{JOR} &= (D/\omega)^{-1}\left((1/\omega-1)D+L+U\right). \end{aligned}$$

## Definition

**Extended** *p***-normed algebraic distance** between *i* and *j* after *k* iterations  $x^{(k+1)} = Hx^{(k)}$  on *R* random initializations

$$\rho_{ij}^{(k)} := \left(\sum_{r=1}^{R} |x_i^{(k,r)} - x_j^{(k,r)}|^p\right)^{1/p}$$

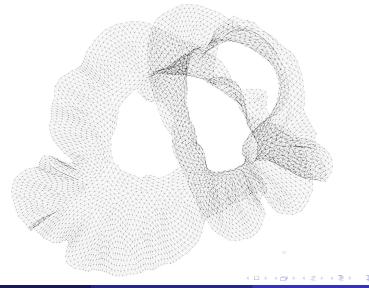

## Algebraic distance is inspired by **Bootstrap Algebraic Multigrid**

I. Safro (Clemson)

- convergence properties of H
- how to choose x<sup>(0)</sup>
- properties of early iterations
- special focus on JOR
- define "Mutually Reinforcing Model" of graph vertices and their neighborhoods
- describe this model using JOR

#### Theorem

Given a connected graph, let  $(\mu_i, \hat{v}_i)$  be the eigen-pairs of (L, D), labeled in nondecreasing order of the eigenvalues, and assume that  $\mu_2 \neq \mu_3 \neq \mu_{n-1} \neq \mu_n$ . Unless  $\omega = 2/(\mu_2 + \mu_n)$ ,  $\hat{s}_{ij}^{(k)}$  will always converge to a limit  $|(e_i - e_j)^T \xi|$  in the order  $O(\theta^k)$ , for some  $\xi$  and  $0 < \theta < 1$ .

(i) If 
$$0 < \omega < \frac{2}{(\mu_3 + \mu_n)}$$
, then  $\xi \in \text{span}\{\hat{v}_2\}$  and  $\theta = \frac{1 - \omega \mu_3}{1 - \omega \mu_2}$ ;  
(ii) If  $\frac{2}{(\mu_3 + \mu_n)} \le \omega < \frac{2}{(\mu_2 + \mu_n)}$ , then  $\xi \in \text{span}\{\hat{v}_2\}$  and  $\theta = -\frac{1 - \omega \mu_n}{1 - \omega \mu_2}$ ;  
(iii) If  $\frac{2}{(\mu_2 + \mu_n)} < \omega < \min\{\frac{2}{(\mu_2 + \mu_{n-1})}, \frac{2}{\mu_n}\}$ , then  $\xi \in \text{span}\{\hat{v}_n\}$  and  $\theta = -\frac{1 - \omega \mu_2}{1 - \omega \mu_n}$ ;  
(iv) If  $\frac{2}{(\mu_2 + \mu_{n-1})} \le \omega < \frac{2}{\mu_n}$ , then  $\xi \in \text{span}\{\hat{v}_n\}$  and  $\theta = \frac{1 - \omega \mu_{n-1}}{1 - \omega \mu_n}$ .

#### Theorem

Given a graph, let  $(\mu_i, \hat{v}_i)$  be the eigen-pairs of (L, D), labeled in nondecreasing order of the eigenvalues. Denote  $\hat{V} = [\hat{v}_1, \dots, \hat{v}_n]$ . Let  $x^{(0)}$  be the initial vector of the JOR process, and let  $a = \hat{V}^{-1}x^{(0)}$  with  $a_1 \neq 0$ . If the following two conditions are satisfied:

$$1 - \omega \mu_n \ge 0$$
 and  $f_k := \frac{\alpha r_k^{2k} (1 - r_k)^2}{1 + \alpha r_k^{2k} (1 + r_k)^2} \le \frac{1}{\kappa}$ ,

where  $\alpha = \left(\sum_{i \neq 1} a_i^2\right) / (4a_1^2)$ ,  $r_k$  is the unique root at [0, 1] of

$$2\alpha r^{2k+2} + 2\alpha r^{2k+1} + (k+1)r - k = 0,$$

then 
$$1 - \left\langle \frac{x^{(k)}}{\|x^{(k)}\|}, \frac{x^{(k+1)}}{\|x^{(k+1)}\|} \right\rangle^2 \le \frac{4 \operatorname{cond}(D) f_k}{(1 + \operatorname{cond}(D) f_k)^2}$$

A > + = + + =

## Sketch of Theorems

- We cannot use H<sub>JAC</sub> for bipartite components. Other iteration matrices are convergent with particular ω.
- JOR: Given a connected graph, let (μ<sub>i</sub>, v̂<sub>i</sub>) be the eigen-pairs of the matrix pencil (L, D). The normalized algebraic distance will converge either to span{v̂<sub>2</sub>} or span{v̂<sub>n</sub>}.
- JOR: Usually, the convergence will be slow. For example, in many cases it will be  $O\left(\left|\frac{\sigma_3}{\sigma_2}\right|^k\right)$ , where  $\sigma_i$  is an eigenvalue of  $H_{JOR}$ .
- JOR: However, after small number of iterations (k), x<sup>(k)</sup> will be very close to x<sup>(k+1)</sup>.

16/34

• • • • • • • • • • • • • •

A mutually reinforcing environment:

Everybody is influenced by its neighbors:

$$x_i = \mu x_i + \sum_j \left( \frac{w_{ij}}{\sum_k w_{ik}} \right) x_j.$$

•  $0 \leq \mu \leq 1$ :

- When  $\mu$  is close to zero, the environment plays a major role.
- When  $\mu$  is close to one, the entities are stubborn.
- $\mu$  is a property of the entire environment.
- Two entities x<sub>i</sub> and x<sub>i</sub> are close/similar if

$$|x_i - x_j|$$
 is small.

A D b 4 A b

Matrix form of the model

$$\mathbf{x} = \mu \mathbf{x} + \mathbf{D}^{-1} \mathbf{W} \mathbf{x},$$

or

$$Lx = \mu Dx$$
 ( $0 \le \mu \le 1$ ).

Possibilities:

μ = 0, x = 1. A strong reinforcing environment, but no discriminating power.

•  $\mu = \mu_2$ ,  $x = \hat{v}_2$ . Good. ( $\mu_2$  usually close to zero.)

The limit of the scaled algebraic distance  $\hat{s}_{ij}^{(k)}$  exactly meets the second possibility.

$$\hat{\pmb{s}}_{ij}^{(k)} 
ightarrow \left| (\pmb{e}_i - \pmb{e}_j)^T \hat{\pmb{v}}_2 \right|.$$

At an early stage of the iterations (assuming that the iterates are normalized):

$$x^{(k)} \approx x^{(k+1)} = rac{H_{JOR} x^{(k)}}{ ext{normalization}} pprox rac{(I - \omega D^{-1}L) x^{(k)}}{1 - \omega \mu_2}.$$

Simplified to

$$x^{(k)} \approx \mu_2 x^{(k)} + D^{-1} W x^{(k)}.$$

This means that  $x^{(k)}$  approximately satisfies the model.

Conclusion:  $\hat{v}_2$  is good.  $x^{(k)}$  is also good. They both fit the mutually reinforcing model.
