

Names for certain domains.

$\mathbb{N} = \{0, 1, 2, 3, \dots\}$ are the *natural numbers*

$\mathbb{Z} = \mathbb{N} \cup -\mathbb{N}$ are the *integers*

$\mathbb{Q} = \{a/b : a \in \mathbb{Z}, 0 < b \in \mathbb{Z}, \text{ and } \gcd a, b = 1\}$ are the *rational numbers*

\mathbb{R} are the *real numbers*.

\mathbb{C} are the *complex numbers*.

For any ring R , $R[x]$ is the ring of polynomials with coefficients in R .

Let S be a set and consider the following operators on S ,

$+$: $S \times S \rightarrow S$ (binary sum)

0 : $\rightarrow S$ (nullary zero element)

$-$: $S \rightarrow S$ (unary negation)

\times : $S \times S \rightarrow S$ (binary product). Often we write ab for $a \times b$)

1 : $\rightarrow S$ (nullary identity element)

$^{-1}$: $S^* \rightarrow S^*$, where $S^* = S - \{0\}$. (unary inverse)

The following properties are often encountered. These assertions are for all $a, b, c \in S$,

- $P1 : (a + b) + c = a + (b + c)$, additive associativity
- $P2 : a + 0 = a = 0 + a$, (2-sided) additive identity element
- $P3 : a + (-a) = 0 = (-a) + a$, (2-sided) additive inverses
- $P4 : a + b = b + a$, additive commutativity
- $P5 : (a \times b) \times c = a \times (b \times c)$, multiplicative associativity
- $P6 : a \times 0 = 0 = 0 \times a$, (2-sided) absorbing element ("zero" element)
- $P7 : a \times 1 = a = 1 \times a$, (2-sided) multiplicative identity element
- $P8 : a \times b = b \times a$, multiplicative commutativity
- $P9 : a \times b = 0$ if and only if $a = 0$ or $b = 0$ (no zero divisors)
- $P10 : \text{Ascending chain condition, Noetherian domain}$
- $P11 : \text{Unique Factorization property}$
- $P12 : \text{Every ideal is principal}$
- $P13 : \text{Let } S^* \text{ denote the set of nonzero elements in } S. \exists d : S^* \rightarrow \mathbb{R}^+ \text{ such that}$
 - $P13a : d(a) >= 0 \forall a \in S^*$.
 - $P13b : d(ab) >= d(a), \forall a, b \in S^*$.
 - $P13c : \forall a, b > 0, \exists q, r \in S \text{ such that } a = qb + r \text{ and } (r = 0 \text{ or } d(r) < d(b)).$
- $P14 : \text{If } a \neq 0, \exists b \in S \text{ such that } a \times b = 1 = b \times a$, (2-sided) inverses.
The inverse is normally denoted as a^{-1}

- $D = (S, +)$, such that P1 is a *semi-group*.
- $D = (S, +, 0)$, such that P1,P2 is a *monoid*.
- $D = (S, +, 0, -)$, such that P1,P2,P3 is a *group*.
- $D = (S, +, 0, -)$, such that P1,P2,P3,P4 is an *abelian* (or commutative) *group*.
- $D = (S, +, 0, -, \times)$, such that P1,P2,P3,P4,P5,P6 is a *ring*.
- (Remark: A ring is a group additively and a monoid multiplicatively.)
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8 is a *commutative ring with 1*, or CR1, for short.
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8,P9 is an *integral domain*, ID.
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8,P9,P10,P11 is a *unique factorization domain*, UFD.
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8,P12 is a *principal ideal ring*, PIR.
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8,P9,P12 is a *principal ideal domain*, PID.
- $D = (S, +, 0, -, \times, 1)$, such that P1,P2,P3,P4,P5,P6,P7,P8,P9,P13 is an *Euclidean domain*, ED.
- $D = (S, +, 0, -, \times, 1, ^{-1})$, such that P1,P2,P3,P4,P5,P6,P7,P8,P9,P14 is a *field*.

Theorem: $field \subset ED \subset PID \subset UFD \subset ID \subset CR1 \subset ring$,
and $PIR \subset CR1$.

Further definitions:

An element a in a CR1 D is a *unit* if $\exists b \in D$ such that $ab = 1$. Such a b is called the *inverse* of a and is normally written a^{-1} . Lemma: If such b exists it is unique.

Elements a and b in an ID, D , are *associates* if \exists unit $u \in D$ such that $au = b$.

With respect to elements $a, b \in D$, a CR1:

An a is said to *divide* b if $\exists c \in D : a \times c = b$, and we write $a|b$ in this case.

An element a is said to be a *zero divisor* if $\exists c \neq 0 : a \times c = 0$.

Be careful: $a|0$ is true of all a (let $c = 0$), but more often than not, a is not a zero divisor!

Remarks and examples

Fields are our bread and butter. Examples are $\mathbb{Q}, \mathbb{R}, \mathbb{C}, \mathbb{Z}_p$, for prime p .

ED's are important because the quotient/remainder is a basis for an extended greatest common divisor (EGCD) algorithm. Examples are $\mathbb{Z}, F[x]$, for field F .

PID's are PIR's with no zero divisors. No important examples that aren't EDs.

PIR's are important because this is the most general class of rings in which EGCD is defined: For every a, b there exists d, s, t such that $d = \gcd(a, b) = sa + tb$. Example is \mathbb{Z}_n , for composite n .

UFD's are important because factorization is important. Example: $F(x, y)$, multivariate polynomials over a field. Note, $\gcd(a, b)$ exists (is well defined) in a UFD, but in general, extended gcd is not.

ID's are important because lack of zero divisors implies a cancellation law: $ab = ac$ and $a \neq 0 \Rightarrow b = c$.

CR1's are important because some basic definition (eg. matrix determinant) and algorithms (eg. most matrix multiplication schemes) are valid at this generality.
